

# **ELEC-E8125 Reinforcement Learning Actor-critic methods**

Ville Kyrki 29.10.2019

## **Today**

- Combining policy gradient with value functions
  - → actor-critic methods

## **Learning goals**

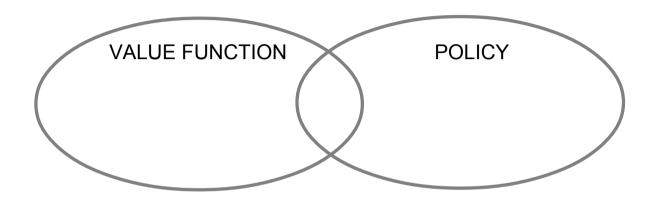

Understand basis of actor-critic approaches.

- Even with value function approximation, large state spaces can be problematic.
- Learning parametric policies  $\pi(u|x,\theta)$  directly without learning value functions sometimes easier.

 Non-Markov (partially observable) or adversarial situations might benefit from stochastic policies.

#### Value-based vs policy-based RL

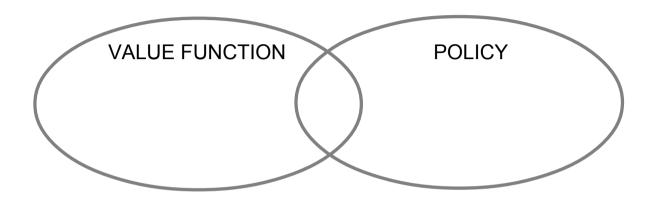

Value-based

- · Learnt value function.
- · Implicit policy.

Policy-based

- · No value function.
- · Learnt policy.

#### Value-based vs policy-based RL

Value-based

- · Learnt value function.
- · Implicit policy.

Actor-critic

- · Learnt value function.
- · Learnt policy.

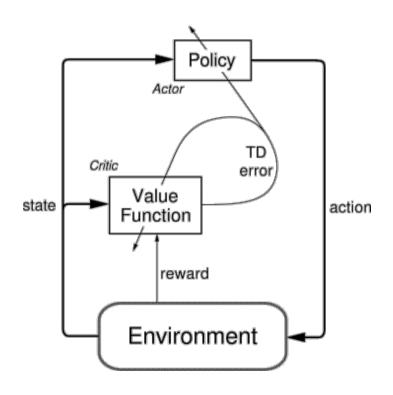

Policy-based

- · No value function.
- · Learnt policy.

### **Actor-critic approach – overview**

- Critic estimates value function.
- Actor updates policy in direction of critic.
- For policy gradient, critic estimates value function.
  - See previous lectures.

### Policy gradient - recap

#### REINFORCE

- 1. Run policy, collect  $\{\tau_i\}$   $\tau_i = (x_0^i, u_0^i, r_0^i, x_1^i, u_1^i, r_1^i, ...)$
- 2.  $\nabla_{\theta} R(\theta) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) \left( \sum_{t'=t}^{T} r(\boldsymbol{x}_{t'}^{i}, \boldsymbol{u}_{t'}^{i}) \right) \right)$
- 3.  $\theta \leftarrow \theta + \alpha \nabla_{\theta} R(\theta)$

### Policy gradient – recap

#### REINFORCE

1. Run policy, collect  $\{\tau_i\}$   $\tau_i = (x_0^i, u_0^i, r_0^i, x_1^i, u_1^i, r_1^i, ...)$ 

2. 
$$\nabla_{\theta} R(\theta) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) \left( \sum_{t'=t}^{T} r(\boldsymbol{x}_{t'}^{i}, \boldsymbol{u}_{t'}^{i}) \right) \right)$$

3.  $\theta \leftarrow \theta + \alpha \nabla_{\theta} R(\theta)$ 

What's this? Value function

Does it look familiar?

### Policy gradient – recap

#### REINFORCE

1. Run policy, collect  $\{\tau_i\}$   $\tau_i = (x_0^i, u_0^i, r_0^i, x_1^i, u_1^i, r_1^i, ...)$ 

2. 
$$\nabla_{\theta} R(\theta) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) \left( \sum_{t'=t}^{T} r(\boldsymbol{x}_{t'}^{i}, \boldsymbol{u}_{t'}^{i}) \right) \right)$$
3.  $\theta \leftarrow \theta + \alpha \nabla_{\theta} R(\theta)$ 

What's this?
Does it look familiar?

$$Q_{\pi}(x_{t}, u_{t}) = \sum_{t=t}^{T} E[r(x_{t}^{i}, u_{t}^{i})|x_{t}, u_{t}]$$

Q is true expected reward, unlike the estimate in step 2. This would reduce variance of the gradient estimate.

$$\nabla_{\boldsymbol{\theta}} R(\boldsymbol{\theta}) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\boldsymbol{\theta}} \log \pi_{\boldsymbol{\theta}}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) Q(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) \right)$$

$$\nabla_{\boldsymbol{\theta}} R(\boldsymbol{\theta}) = E_{\boldsymbol{\theta}} [\nabla_{\boldsymbol{\theta}} \log p_{\boldsymbol{\theta}}(\boldsymbol{\tau}) (R(\boldsymbol{\tau}) - \boldsymbol{b})]$$

#### Remember the baselines?

$$\nabla_{\theta} R(\theta) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) \left( Q(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) - b \right) \right)$$

Average is a good baseline:  $b_t = \frac{1}{J} \sum_{i=1}^{J} Q(x_t^i, u_t^i)$ 

But what does the average mean here?

$$\nabla_{\boldsymbol{\theta}} R(\boldsymbol{\theta}) = E_{\boldsymbol{\theta}} [\nabla_{\boldsymbol{\theta}} \log p_{\boldsymbol{\theta}}(\boldsymbol{\tau}) (R(\boldsymbol{\tau}) - \underline{b})]$$

#### Remember the baselines?

$$\nabla_{\theta} R(\theta) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) \left( Q(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) - b \right) \right)$$

Average is a good baseline: 
$$b_t = \frac{1}{J} \sum_{i=1}^{J} Q(x_t^i, u_t^i)$$
 Expectation of the return

But what does the average mean here?

b approximates the state value function V(x)!

$$\nabla_{\boldsymbol{\theta}} R(\boldsymbol{\theta}) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\boldsymbol{\theta}} \log \pi_{\boldsymbol{\theta}}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) \left( Q(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) - V(\boldsymbol{x}_{t}^{i}) \right) \right)$$

$$\nabla_{\boldsymbol{\theta}} R(\boldsymbol{\theta}) = E_{\boldsymbol{\theta}} [\nabla_{\boldsymbol{\theta}} \log p_{\boldsymbol{\theta}}(\boldsymbol{\tau}) (R(\boldsymbol{\tau}) - \underline{b})]$$

#### Remember the baselines?

$$\nabla_{\theta} R(\theta) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta} (\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) \left( Q(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) - b \right) \right)$$

Average is a good baseline:  $b_t = \frac{1}{J} \sum_{i=1}^{J} Q(x_t^i, u_t^i)$ 

But what does the average mean here?

b approximates the state value function V(x)!

$$\nabla_{\theta} R(\theta) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) A(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) \right)$$

### **Determining the advantage**

How to find a good estimate for this?

$$\nabla_{\boldsymbol{\theta}} R(\boldsymbol{\theta}) \approx \frac{1}{J} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\boldsymbol{\theta}} \log \pi_{\boldsymbol{\theta}}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) A(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) \right) \quad \text{Estimate Q, V, or A?}$$

*V* has the fewest parameters, so let's estimate it (from data). But how to then get *A*?

$$A(\mathbf{x}_{t}, \mathbf{u}_{t}) = Q(\mathbf{x}_{t}, \mathbf{u}_{t}) - V(\mathbf{x}_{t})$$

$$Q(\mathbf{x}_{t}, \mathbf{u}_{t}) = r(\mathbf{x}_{t}, \mathbf{u}_{t}) + E_{\mathbf{x}_{t+1} \sim \pi(\mathbf{x}_{t+1} | \mathbf{x}_{t}, \mathbf{u}_{t})} [V(\mathbf{x}_{t+1})]$$

$$A(\mathbf{x}_{t}, \mathbf{u}_{t}) \approx r_{(\mathbf{x}_{t}, \mathbf{u}_{t})} + V(\mathbf{x}_{t}) + V(\mathbf{x}_{t+1})$$

Thus, knowing *V* allows approximating *A*.

## Fitting value functions (mostly recap)

- Episodic batch fitting: (1) gather data, (2) fit (least squares) over gathered data.
- squares) over gaunerous...

   Data = state-value pairs  $\left\{\left(x_{t}^{i}, \sum_{t'=t}^{T} r_{t'}^{i}\right)\right\}$
- Requires episodic environments to get the value.
- Fitting criterion  $L(\phi) = \sum_{i} ||V_{\phi}(\mathbf{x}_{i}) y_{i}||^{2}$

Any parametric function approximator

### Fitting value functions (mostly recap)

- Non-episodic batch fitting: (1) gather data, (2) fit (least squares) over gathered data.
- Data = state-value pairs  $\{(x_t^i, r_t^i + V(x_{t+1}^i))\}$
- Identical fitting criterion

$$L(\phi) = \sum_{i} \|V_{\phi}(\mathbf{x}_{i}) - y_{i}\|^{2}$$

Any parametric function approximator

### Wrap-up: A batch TD actor critic

#### Batch actor-critic

- 1. Run policy, collect  $\{\tau_i\}$   $\tau_i = (x_0^i, u_0^i, r_0^i, x_1^i, u_1^i, r_1^i, ...)$
- 2. Fit  $V_{\phi}(x_t)$
- 3. Evaluate  $A(\mathbf{x}_t, \mathbf{u}_t) \approx r_{(\mathbf{x}_t, \mathbf{u}_t)} + V_{\phi}(\mathbf{x}_t) V_{\phi}(\mathbf{x}_{t+1})$
- 4. Evaluate  $\nabla_{\theta} R(\theta) \approx \frac{1}{I} \sum_{i=1}^{J} \left( \sum_{t=0}^{T} \nabla_{\theta} \log \pi_{\theta}(\boldsymbol{u}_{t}^{i} | \boldsymbol{x}_{t}^{i}) A(\boldsymbol{x}_{t}^{i}, \boldsymbol{u}_{t}^{i}) \right)$
- 5. Update  $\theta \leftarrow \theta + \alpha \nabla_{\theta} R(\theta)$

## An on-line TD actor critic (with discount)

learning

rate

On-line actor-critic

- 1. Take action  $u = \pi(u|x)$
- 2. Update  $V_{\phi}(x_t)$  using  $\phi \leftarrow \phi + \beta |r_t + \gamma V_{\phi}(x_{t+1}) V_{\phi}(x_t)|\nabla_{\phi} V_{\phi}(x_t)$
- 3. Evaluate  $A(x_t, u_t) \approx r_{(x_t, u_t)} + \sqrt{Y} Y(x_t) + V(x_{t+1})$
- 4. Evaluate  $\nabla_{\theta} R(\theta) \approx \nabla_{\theta} \log \pi_{\theta}(\mathbf{u}_{t}^{i} | \mathbf{x}_{t}^{i}) A(\mathbf{x}_{t}^{i}, \mathbf{u}_{t}^{i})$
- 5. Update  $\theta \leftarrow \theta + \alpha \nabla_{\theta} R(\theta)$

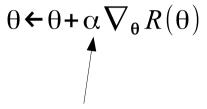

In practice, even this works best in batches (decreases variance in gradient estimates).

From lecture 5!

Note: TD estimate can be biased.

#### **Challenge: Gradient step sizes**

<u>Gradient step size</u> affects convergence (speed) greatly but is difficult to set.

Incorrect step size may lead to divergence or slow convergence.

How to guarantee policy improvement?

# Reformulating policy gradient through surrogate advantage

- How to predict performance of updated policy (since we do not have data about it yet)?
- Surrogate advantage  $R_{\theta_{old}}^{IS}(\theta)$  approximates performance difference between previous and updated policies

$$R_{\theta_{old}}^{IS}(\theta) = E_{\tau \sim \pi_{\theta_{old}}} \left[ \frac{\pi_{\theta}(\boldsymbol{u}_{t}|\boldsymbol{x}_{t})}{\pi_{\theta_{old}}(\boldsymbol{u}_{t}|\boldsymbol{x}_{t})} A^{\pi_{\theta_{old}}}(\boldsymbol{x}_{t}, \boldsymbol{u}_{t}) \right]$$

See the importance sampling in effect!

### **Bounding surrogate advantage**

Result: Policy is guaranteed to improve by optimizing

$$max_{\theta} \left( R_{\theta_{old}}^{IS}(\theta) - c \mathcal{D}_{KL}^{max}(\theta_{old}, \theta) \right)$$

where

known constant

$$D_{\mathit{KL}}^{\mathit{max}}ig( heta_{\mathit{old}}$$
 ,  $oldsymbol{ heta}ig)$ 

is the maximum Kullback-Leibler divergence between the policies.

In practice leads to slow convergence, not easy to optimize.

# Trust region policy optimization (Schulman et al. 2015)

Instead of lower bound, optimize surrogate advantage and constrain KL-divergence:

$$max_{\theta}R_{\theta_{ald}}^{IS}(\theta)$$

such that

$$ar{D}_{\mathit{KL}}( heta_{\mathit{old}}, heta) \! \equiv \! E_{ au \sim \pi_{ heta_{\mathit{old}}}} \! \left[ D_{\mathit{KL}}(\pi_{ heta}(.|oldsymbol{x}), \pi_{ heta_{\mathit{old}}}(.|oldsymbol{x})) 
ight] \! \leq \! \delta$$

Intuition: Limit the policy parameter change such that the actions do not change too much in the relevant part of state space.

In practice, this is still (too) costly to compute and the constraint is approximated (details in the paper).

# Proximal policy optimization (Schulman et al. 2017)

Remember the surrogate advantage?

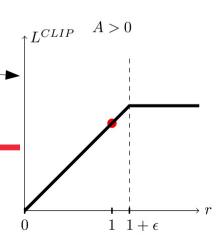

$$R_{\theta_{old}}^{IS}(\theta) = E_{\tau \sim \pi_{\theta_{old}}} \left[ \frac{\pi_{\theta}(\boldsymbol{u}_{t}|\boldsymbol{x}_{t})}{\pi_{\theta_{old}}(\boldsymbol{u}_{t}|\boldsymbol{x}_{t})} A^{\pi_{\theta_{old}}}(\boldsymbol{x}_{t}, \boldsymbol{u}_{t}) \right]$$

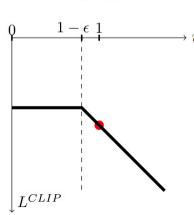

Optimize instead

$$L^{CLIP}(\theta) = E_{\tau \sim \pi_{\theta_{old}}} \left[ \min(g_t(\theta) A, clip(g_t(\theta), 1 - \epsilon, 1 + \epsilon) A) \right]$$

Looks horrible, look at the figure instead.
In practice: Limit how much benefit there is for changes.

A < 0

## Proximal policy optimization (Schulman et al. 2017)

Other variants possible

#### **Algorithm**: PPO

for i = 1, 2, ... do

Run policy, collect trajectories  $\{ \mathbf{\tau}_i \}$   $\mathbf{\tau}_i = (\mathbf{x}_0^i, \mathbf{u}_0^i, r_0^i, \mathbf{x}_1^i, \mathbf{u}_1^i, r_1^i, \dots)$ 

Compute advantage estimates  $A(x_t, u_t) \approx r_{(x_t, u_t)} + \gamma V(x_t) - V(x_{t+1})$ 

using current value function  $V_{\phi}(x_t)$  Update policy by maximizing  $L^{CLIP}(\theta)$  for K epochs of stochastic gradient ascent

Fit  $V_{\phi}(x_t)$  by minimizing  $L(\phi) \equiv \sum_i ||V_{\phi}(x_i) - y_i||^2$  using gradient descent

#### **Summary**

- Actor-critic approaches allow addressing continuing problems and continuous action spaces.
- They may also learn faster than policy gradient because variance of policy gradient estimate is reduced.
- TRPO/PPO aim to control extent of policy update steps to avoid oscillation/divergence due to large updates.

#### **Next: Model-based RL**

- Even with critic, policy-based approaches often require huge amounts of data.
- Can we somehow benefit even more from earlier experiences?
- Reading: no readings.
